

Disentangling the Meanings of Diversity and Inclusion in Organizations

QUINETTA M. ROBERSON

Cornell University

Given the emergence of a new rhetoric in the field of diversity, which replaces the term *diversity* with the term *inclusion*, this study comparatively investigates the meanings of diversity and inclusion in organizations. The findings of Study 1, which used a qualitative methodology to explore the construct definitions and to derive a measure of attributes to support diversity and inclusion, revealed conceptually distinct definitions. The reliability and factor structure of the scale was evaluated in Study 2 and cross-validated in Study 3. The results supported a five-factor model of diversity and inclusion and suggest a distinction between the concepts, although the terms may not describe separate types of work environments but different approaches to diversity management.

Keywords: diversity; diversity management; inclusion; construct validation

Consistent with labor predictions, the workforce of the 21st century may be characterized by increased numbers of women, minorities, ethnic backgrounds, intergenerational workers, and different lifestyles (Langdon, McMenamin, & Krolik, 2002). Furthermore, organizations have realized that the extent to which these demographic workforce changes are effectively and efficiently managed will affect organizational functioning and competitiveness (Harvey, 1999; Kuczynski, 1999). As demonstrated by the more than 75% of *Fortune* 1000 companies that have instituted diversity initiatives (Daniels, 2001), the management of diversity has become an important business imperative. Despite a pervasive awareness of the need for management to concern itself with diversity-related issues, organizations have

The author's sincerest appreciation is extended to Martin Davidson, Alison Konrad, Ellen Ernst Kossek, and Belle Rose Ragins for their helpful comments on earlier versions of this article. In addition, the author gratefully acknowledges the Workplace Diversity Network and National Conference for Community and Justice for their financial and administrative support on this project. 212

adopted different approaches to diversity management. Common perspectives on managing diversity focus on targeted recruitment initiatives, education and training, career development, and mentoring programs to increase and retain workforce heterogeneity in organizations (Cox, 1993; Morrison, 1992). However, some organizations have begun to rely on a broader set of programs and initiatives including employee participation, communication strategies, and community relations (Wentling & Palma-Rivas, 2000), which emphasize the removal of barriers that block employees from using the full range of their skills and competencies in organizations (Harvey, 1999). As such, some organizations espouse a focus on inclusion in the management of diversity (Mehta, 2000).

Despite this move from diversity to inclusion in the practitioner literature, we have a limited understanding of whether it represents a material change in organizational actions and outcomes, or simply a change of phrasing to reduce backlash against the same initiatives (Linnehan & Konrad, 1999). Some research, which explores varying organizational approaches to diversity management, suggests that there are practical differences in focusing on diversity and inclusion. For example, Cox (1991) and Thomas and Ely (1996) propose typologies that distinguish between organizations and their diversity management paradigms based on the degree to which diversity exists and is integrated into organizational structures, strategies, and processes. Research on diversity climates, which highlights workforce demography, personal value for and comfort with diversity, fairness, and inclusion as dimensions of employees' diversity climate perceptions, also suggests a distinction between the concepts of diversity and inclusion (Kossek & Zonia, 1993; Mor Barak, Cherin, & Berkman, 1998). However, little research has empirically investigated the specific attributes and practices for diversity and inclusion in organizations. The results of a study by Pelled and her colleagues (Pelled, Ledford, & Mohrman, 1999), which examined and found support for decision-making influence, access to information, and job security as indicators of workplace inclusion, provide some understanding of the construct of inclusion and practices to support inclusion in organizations. Yet, research is needed to explore additional indicators of inclusion as well as to explore how indicators of inclusion parallel, or differ from, indicators of diversity.

This study comparatively investigates the meanings of diversity and inclusion in organizations. First, I review definitions of diversity and inclusion and related research that explores the dimensionality of these constructs. I then describe three studies to develop and evaluate a scale for measuring attributes for diversity and for inclusion in organizations. In Study 1, information on these constructs was solicited from a sample of *Fortune* 500 organizations to generate items for the scale. The reliability and factor structure of

the scale was evaluated using a sample of diversity professionals in Study 2 and retested using a sample of organizational development professionals in Study 3. I conclude with a discussion of the theoretical and practical implications of this research as well as directions for further research.

THEORETICAL BACKGROUND

In the organizational literature, diversity has been used to describe the composition of groups or workforces. For example, diversity is considered to be a characteristic of groups that refers to demographic differences among members (McGrath, Berdahl, & Arrow, 1995). Similarly, Larkey (1996) defines diversity as differences in perspectives resulting in potential behavioral differences among cultural groups as well as identity differences among group members in relation to other groups. Represented by particular differences of varying cultural significance (Cox, 1993), diversity may be defined in terms of observable and nonobservable characteristics (see Milliken & Martins, 1996). Observable dimensions include such characteristics as gender, race, ethnicity, and age, which are legally protected from discrimination, particularly in the United States. However, definitions and measurements of diversity have evolved to include a wider array of nonobservable characteristics that include cultural, cognitive, and technical differences among employees (Kochan et al., 2003). For example, research has shown underlying attributes such as education, functional background, organizational tenure, socioeconomic background, and personality to influence patterns of interaction between group members (Jackson, May, & Whitney, 1995; Tsui, Egan, & O'Reilly, 1992). Thus, the concept of diversity more accurately represents "the varied perspectives and approaches to work that members of different identity groups bring" (Thomas & Ely, 1996, p. 80).

Research suggests that by focusing on the advantages of employing members of different identity groups in organizations, the theme of diversity largely ignores the dynamics and consequences of exclusion (Prasad, 2001). More specifically, by approaching diversity management as activities related to the hiring and utilization of personnel from different cultural and social backgrounds (Cox & Blake, 1991), current research has assumed the inclusion of diverse individuals into organizations. Thus, little attention has been given to the concept of inclusion in the organizational literature. Given research that shows that individuals from diverse social and cultural groups are often excluded from networks of information and opportunity in organizations (Ibarra, 1993; Pettigrew & Martin, 1989), inclusion has been used in other areas to describe worker participation and empowerment. For example,

Mor Barak and Cherin (1998) define inclusion as the extent to which individuals can access information and resources, are involved in work groups, and have the ability to influence decision-making processes. Rather than emphasizing difference as an organizational commodity that has exchange value in terms of economic performance, inclusion is focused on the degree to which individuals feel a part of critical organizational processes. Thus, inclusion represents a person's ability to contribute fully and effectively to an organization (Miller, 1998; Mor Barak & Cherin, 1998).

Researchers have proposed different organizational approaches to the management of diversity that incorporate the definitional distinction between diversity and inclusion. For example, Cox (1991) proposed a typology of organizations based on the degree of acculturation, structural and informal integration, lack of cultural bias, organizational identification, and intergroup conflict, which are considered to be conditions that influence whether organizations can fully realize the value in diversity. More specifically, Cox (1991) suggests that organizations can be characterized as monolithic, plural, or multicultural, which differ based on the level of structural and cultural inclusion of employees across varying group memberships. Thus, while plural organizations may be characterized by a focus on employment profiles (i.e., workforce composition) and fair treatment, multicultural organizations may be characterized by policies and practices that facilitate the full utilization of human resources and enhance employees' abilities to contribute to their maximum potential.

Thomas and Ely (1996) also proposed a typology of organizational approaches to diversity that can be distinguished based on the degree to which diversity is considered as the varied knowledge and perspectives that members of different identity groups bring and is incorporated into the organization's strategies, operations, and practices. More specifically, Thomas and Ely identify the discrimination-and-fairness paradigm, which involves a focus on equal opportunity, fair treatment, recruitment, and compliance, and the access-and-legitimacy paradigm, which focuses on matching workforce demographics with those of key consumer groups to expand and better serve specialized market segments, as the most common approaches to diversity management. However, they highlight a new, emerging approach—the learning-and-effectiveness paradigm—which links diversity to organizational strategy, markets, processes, and culture. More specifically, diverse employee perspectives and approaches are incorporated into business processes to leverage the benefits of diversity to enhance organizational learning and growth. Thus, whereas organizations functioning under the other paradigms approach the management of diversity from assimilation and/or dif-

ferentiation perspectives, those under a learning-and-effectiveness paradigm are organized around the overarching theme of integration and inclusion.

Although research distinguishes between concepts of diversity and inclusion through the articulation of different organizational cultures and systems, little research has empirically investigated the specific attributes and practices for diversity and inclusion in organizations. Ely and Thomas (2001) investigated the effects of their proposed diversity management paradigms on work group functioning in a qualitative study of three professional services organizations. Although the results provided support for these varying approaches to diversity management and their relationships to specific group outcomes, the study's design was intended for theory development concerning diversity management paradigms rather than for examining the practices and processes that may support each paradigm. Thus, this study attempts to build on Ely and Thomas's work by using a more generalizable sample of organizations to explore the structures, systems, and policies that support diversity and inclusion.

A small body of research on diversity climates, which refers to employee perceptions of the organizational context related to women and minorities (Kossek & Zonia, 1993; Mor Barak et al., 1998), offers some insight into the meanings of diversity and inclusion. Kossek and Zonia (1993) explored the effects of organizational and group characteristics on employee perceptions of diversity climate, which was described as the value placed by employees on efforts to promote diversity in an organization and their attitudes toward the beneficiaries of these efforts. More specifically, diversity climates were assessed as employee perceptions of the relationship between organizational excellence and the recruitment and retention of women and minorities, their qualifications and performance, and their access to resources and rewards in comparison to others. Using a sample of faculty and academic staff at a university with a demonstrated commitment to diversity, the authors found support for the proposed dimensions of diversity climate, which emerged to explain 66% of the variance. More important, the results of Kossek and Zonia's study highlight workforce composition and equality as components of employees' diversity climate perceptions. Mor Barak et al. (1998) also examined the composition of diversity climates, which was represented as having a personal dimension—individuals' views and feelings toward people who are different from them—and an organizational dimension—management's policies and procedures targeted toward women and minorities. Conducted by measuring employees' perceptions of issues and practices that are important to understanding and managing diversity, the results of the study suggested four dimensions of diversity climate—personal value for

diversity, personal comfort with diversity, organizational fairness, and organizational inclusion—which explained 57% of the variance. Thus, building on Kossek and Zonia's (1993) research, this study identifies personal and organizational dimensions of diversity climate. In addition, the results highlight the influence of specific practices for structurally including or excluding people from diverse backgrounds (i.e., employee network support groups, mentoring programs, diversity awareness training) on employee diversity climate perceptions.

Although research on diversity climates provides some insight into the relationship between diversity and inclusion, only one study in the management literature has empirically investigated the construct of workplace inclusion. Building on prior conceptualizations of inclusion as centrality or one's position within exchange networks (O'Hara, Beehr, & Colarelli, 1994; Schein, 1971), Pelled and her colleagues (1999) defined inclusion as "the degree to which an employee is accepted and treated as an insider by others in a work system" (p. 1014) and examined the relationships between demographic dissimilarity and three indicators of inclusion—the degree of influence that employees have over decisions that affect them at work, the degree to which employees are kept well-informed about the company's business strategies and goals, and the likelihood that employees will retain their jobs. Although the results of the study demonstrated differential effects on inclusion based on type of demographic dissimilarity (e.g., gender, race, tenure, education) (Pelled et al., 1999), the study's findings provided support for decision-making influence, access to information, and job security as indicators of organizational inclusion. However, the authors suggest that further research should broaden the treatment of the inclusion construct to explore other indicators, such as influence over organizational practices. Accordingly, this study takes a more comprehensive approach and examines multiple indicators of inclusion in organizations.

This investigation builds on and extends prior research through a comparative, empirical investigation of the meanings of diversity and inclusion. As suggested by prior research, diversity and inclusion characterize different yet related approaches to the management of diversity. More specifically, diversity focuses on organizational demography, whereas inclusion focuses on the removal of obstacles to the full participation and contribution of employees in organizations. Given these conceptual distinctions, attributes that support each may differ. Thus, three studies were designed to explore the following research questions: (a) What are the meanings of diversity and inclusion? and (b) What are the organizational attributes that identify or support climates for diversity and climates for inclusion?

STUDY 1: SCALE DEVELOPMENT

SAMPLE

The data for this study were obtained from survey responses collected from human resource or diversity officers of 51 large, publicly traded organizations. Participation was solicited from organizational affiliates of a business center established to facilitate a partnership between industry and academe to advance the study of global human resource management. Given that larger organizations tend to have more established and comprehensive diversity initiatives and programs (Wentling & Palma-Rivas, 2000), this sample was chosen because of their experience with the implementation of organizational diversity management practices. Fifty-one of the 58 affiliated companies (88%) voluntarily participated in the study. Participating organizations had an average size of 75,367 employees and represented a variety of industries (classified by single-digit SIC codes): 62.7% in manufacturing; 19.6% in finance, insurance, and real estate; 7.8% in services; 5.9% in transportation, communications, electric, gas, and sanitary services; and 4.0% in retail trade. In addition, respondents for these companies were 72% female, ranged in age from 38 to 62 years, and had an organizational tenure of 2 to 18 years.

PROCEDURES

An e-mail survey was sent to the human resource officers of the center affiliates who were informed that the purpose of the study was to understand the meanings of diversity and inclusion in organizations. For those organizations with diversity officers, the human resource officers were asked to pass the survey on to the appropriate person. The survey contained four open-ended questions, which were as follows: (a) How would you define diversity? (b) How would you define inclusion? (c) What are the attributes of a diverse organization? (d) What are the attributes of an inclusive organization? For their participation, companies were offered a summary of the study results. Respondents were asked to forward the completed survey via e-mail to a research assistant, who was unfamiliar with the diversity literature and blind to the study's purposes.

ANALYSES

The content analysis of definitions and attributes for diversity and inclusion followed an inductive, grounded theory development process (Glaser &

Strauss, 1967). First, two doctoral research assistants (White male and Asian female), who had no prior knowledge of the study's dimensions of interest, independently analyzed the responses to identify key words or themes and developed separate lists of attributes for diversity and inclusion. Although dimensions suggested by the previously reviewed diversity literature were used as a starting point for developing the instrument, the coders were open to the possibility of additional attributes that would evolve from the survey responses. The coders then created one common list of attributes for diverse organizations and attributes for inclusive organizations. Interrater agreement (Cohen's kappa) across all attributes was .86. A third coder independently coded all comments given in the survey to derive a second attribute list. The interrater agreement between the first two coders and the additional coder across all attributes was .81. In cases of disagreement, the coders reviewed the content issues and reached consensus as to how to categorize the attributes listed by respondents.

RESULTS

In the survey, respondents differentiated between the terms *diversity* and *inclusion* and indicated that the terms describe separate types of work environments. Specifically, definitions of diversity focused primarily on differences and the demographic composition of groups or organizations, whereas definitions of inclusion focused on organizational objectives designed to increase the participation of all employees and to leverage diversity effects on the organization. Sample definitions are provided in Table 1.

The content analyses yielded 30 overall attributes for diversity and inclusion in organizations. Several of the attributes identified in the study were similar to those suggested in other diversity studies, namely affirmative action policies, representation of different demographic groups, respect for differences, and diversity education and training (Cox, 1991; Morrison, 1992). There were other attributes, however, that appeared to be representative of broader human resource management systems, such as 360-degree communication and information sharing, participatory work systems and employee involvement, and equitable systems for recognition, acknowledgment, and reward. All 30 attributes were used to generate individual items to assess dimensions of diversity and inclusion. Because the primary objective of this study was to establish content validity, which is the minimum psychometric requirement for measurement adequacy (Schriesheim, Powers, Scandura, Gardiner, & Lankau, 1993), the results should not be taken as providing conclusive evidence for the existence of a particular set of dimensions of diver-

TABLE 1
Sample Definitions of Diversity and Inclusion

Diversity

“The unique differences and similarities that our employees, customers, suppliers, and communities bring to our global business environment.”

“Diversity encompasses the many ways people may differ, including gender, race, nationality, education, sexual orientation, style, functional expertise, and a wide array of other characteristics and backgrounds that make a person unique.”

“Variation in the human capital profile of the organization/people from different races, religions, perspectives, etc. and therefore different cultures, values, beliefs, and reactions to the organizational environment.”

Inclusion

“We define inclusion as seeking out, valuing, and using the knowledge and experiences of diverse employees for business benefit.”

“Recognizing, understanding, and respecting all the ways we differ, and leveraging those differences for competitive business advantage.”

“A competitive business advantage that we build and maintain by leveraging the awareness, understanding, and appreciation of differences in the workplace to enable individuals, teams, and businesses to perform at their full potential.”

“The environment that makes people feel included and considered part of the system.”

sity or inclusion. The question of whether these attributes are an accurate reflection of the underlying constructs or, alternatively, are an artifact of our data collection methods, analyses, or both was addressed in Study 2.

STUDY 2: SCALE CONSTRUCTION

PILOT TEST SAMPLE

The pilot sample included 74 attendees of a 2-day diversity networking forum, which was sponsored by two public organizations to link diversity practitioners and policymakers and facilitate discussion on emerging issues concerning diversity and inclusion. The factor structure of the initial set of items was examined using this sample. Respondents completed questionnaires during one of the forum sessions and responses were anonymous. The sample was 77% female with an average age of 46 years. In addition, respondents were 52% White, 33% Black, 9% Hispanic, 3% Native American, 1% Asian, 1% Middle-Eastern/Indian, and 1% other.

SAMPLE

One thousand twenty surveys were mailed to conference attendees of a national diversity conference held to provide organizational executives with the opportunity to share practical business experiences with managing diversity. Accordingly, this sample was used given their knowledge of, and experiences with, diversity management. Participation in the study was voluntary, and 186 surveys were returned for a response rate of 18.2%. Respondents represented organizations with an average size of 13,522 employees and represented a variety of industries: 29.3% in manufacturing; 28.8% in services; 18.3% in finance, insurance, and real estate; 14.5% in retail trade; 6.2% in transportation, communications, electric, gas, and sanitary services; and 2.9% in wholesale trade. Respondents were 54% female and had an average age of 48 years. In addition, respondents were 52% White, 30% Black, 7% Hispanic, 3% Asian, 2% Middle-Eastern/Indian, 2% Native American, and 4% other.

SURVEY INSTRUMENT

Items were written to represent each of the attributes for diversity and inclusion identified in Study 1. The language for the items was taken from the qualitative survey responses. The survey indicated that the purpose of the study was to understand the meanings of diversity and inclusion in organizations, including the attributes or characteristics that identify those workplaces. Based on definitions of diversity included in prior diversity research as well as reported by respondents in Study 1, *diversity* was described in the survey as the spectrum of human similarities and differences. Accordingly, diversity in organizations would be characterized by the representation of people with a range of similarities and differences. Similarly, *inclusion* was described as the way an organization configures its systems and structures to value and leverage the potential, and to limit the disadvantages, of differences. Accordingly, inclusion in organizations would be characterized by different perspectives and by structures, policies, and practices to recognize and use these perspectives. Because diversity research describes diversity and inclusion as related rather than as mutually exclusive concepts, this study examined the extent to which specific characteristics supported both diversity and inclusion. Thus, respondents were asked to rate the extent to which each attribute describes diverse organizations and inclusive organizations. In other words, respondents were asked to rate each attribute twice (to allow for both a distinction and relationship between the concepts) rather than rating attributes as supportive of either diversity or inclusion (which would imply

no relationship between the concepts). All ratings were made on a 9-point Likert-type scale ranging from *not at all* to *completely*.

The initial survey was administered to the pilot test sample of forum respondents. An exploratory analysis with principal components and varimax rotation was conducted on each set of 30 attributes. However, given the small sample size, the analysis was to assess content adequacy and whether sufficient variance among respondents could be generated for subsequent statistical analysis. Respondents were also asked to comment on the wording of the items. Based on respondent feedback and the analyses, three of the items were omitted from the survey and language adjustments were made to three additional items. Therefore, 54 items (27 items each for diversity and for inclusion) were included in the final survey.

ANALYSIS

An exploratory factor analysis with principal components and varimax rotation was conducted using all 54 attributes simultaneously. Although such analyses have been shown to be susceptible to sample size effects (Schwab, 1980), research has found that a sample size of 150 observations should be sufficient to obtain an accurate solution as long as item intercorrelations are reasonably strong (Guadagnoli & Velicer, 1988). Inspection of the correlation matrix for all items revealed that more than 50% of the correlations were significant at the .05-level, which provides an adequate basis for proceeding to an examination of the factors (Hair, Anderson, Tatham, & Black, 1998).

A latent root criterion was used to determine the number of factors to be retained. Therefore, only those factors having eigenvalues greater than 1 were considered significant. I also examined the scree plot to identify the optimum number of factors that could be extracted before the amount of unique variance begins to dominate the common variance structure (Hair et al., 1998). To ensure that each item represented the construct underlying each factor, a factor weight of .40 was used as the minimum cutoff (Ford, MacCallum, & Tait, 1986). In addition, a .10 difference between the weights for any given item across factors was maintained so that each item was clearly defined by only one factor (Ford et al., 1986).

RESULTS

Although five factors emerged from the analysis, three factors, which accounted for 70.81% of the variance, were retained. Fifty-one of the 54 items were found to load sufficiently ($> .40$) on the three factors. Item descriptions and their factor loadings are shown in Table 2. As shown in the

NOTE: The bold numbers indicate on which factor the item loaded. I = inclusion; D = diversity.

table, three items (“respect for differences,” “accommodation for physical and developmental abilities,” and “employee support groups, networks, or affinity groups”) loaded on two factors. Accordingly, these items were omitted from further analyses. Thus, the final survey included a total of 42 items (24 items each for diversity and for inclusion).

As shown by the results, one of the derived factors was represented by all of the attributes for inclusion. However, the attributes for diversity were separated across two factors. Closer inspection of those items representing each of the diversity factors revealed two different approaches to diversity in organizations. One factor was concerned with employee involvement in work systems as well as learning and growth outcomes that may stem from diversity in organizations. Consistent with Thomas and Ely’s (1996) diversity management paradigms, this factor included learning and effectiveness outcomes resulting from the integration of diversity into work processes (e.g., innovation and creativity, organizational flexibility, etc.) as well as discrimination-and-fairness issues (e.g., fair treatment of all stakeholders, equitable systems, affirmative action initiatives, etc.). Further, by incorporating such organizational attributes as interdependent work arrangements, collaborative conflict resolution processes, and power sharing, all of which

center on employee participation in organizational processes, this factor also highlighted a focus on inclusion. The second diversity factor encapsulated items related to actual diversity and the integration of diversity management into an organization's strategy. Consistent with Thomas and Ely's access-and-legitimacy paradigm, this factor included the representation of different demographic groups both within and outside of organizations. In addition, organizational attributes that highlight top management's support for diversity (e.g., leadership commitment to diversity, diversity mission and goals, etc.) loaded on this factor. The means, standard deviations, correlations, and reliabilities for the three factors derived from the principal component analyses are presented in Table 3.

STUDY 3: SCALE VALIDATION

SAMPLE

Two thousand surveys were mailed to an organizational development interest group of a national human resources professional association. This sample was chosen given their general familiarity with human resource management without a specific interest and/or focus on diversity. Participation in the study was voluntary, and 330 surveys were returned for a response rate of 16.5%. Respondents represented organizations with an average size of 4,701 employees and represented a variety of industries: 47.8% in services; 26.6% in manufacturing; 11.0% in retail trade; 8.9% in public administration; 3.3% in finance, insurance, and real estate; and 1.4% in transportation, communications, electric, gas, and sanitary services; and 1.0% construction. Respondents were 64% female, had an average age of 48 years, and were 81% White, 13% Black, 4% Hispanic, and 2% other.

ANALYSES

Confirmatory factor analyses were performed to examine the stability of the factor structure obtained in Study 2. Structural equation modeling with maximum likelihood estimation (EQS 5 for Windows; Bentler & Wu, 1995) was used to evaluate the fit of the measurement model. As suggested by Brown and Cudeck (1993), several fit indices were used to provide a more complete assessment of model adequacy. The conventional likelihood ratio chi-square test (Brown & Cudeck, 1993) and three normed fit indices—comparative fit index (CFI), incremental fit index (IFI), and the root mean squared error of approximation (RMSEA)—were used to assess overall model adequacy. Models resulting in CFI and IFI values of .90 or higher are considered acceptable (Bagozzi & Yi, 1988). For the RMSEA index, values below .08 are considered indicative of good fit (Hu & Bentler, 1999).

Because an adequate fit does not necessarily mean that a given model is the best explanation of the relationships among the constructs, I also tested several alternative yet theoretically defensible models to address model suitability (Anderson & Gerbing, 1988). I compared alternative models of increasing complexity (from one factor to five factors), which is a technique that addresses possible issues of common method variance (Podsakoff & Organ, 1986). The one-factor model combined all 42 items included on the final survey, whereas the two-factor model separated the items for diversity and for inclusion (21 items each). The four-factor model split the first factor in Study 2 into two constructs (i.e., one factor made up of items indicating employee involvement, learning and growth outcomes, and fair treatment, and one factor made up of items indicating the representation of diverse groups and top management's support for diversity), which were similar to Factors 2 and 3 in Study 2. The five-factor models were based on a combination of the factors revealed in Study 2 as well as the diversity management paradigms proposed by Thomas and Ely (1996). Specifically, one five-factor model (A) maintained a separation of items indicating employee involvement and learning and growth outcomes for diversity and for inclusion (similar to Study 2), whereas the other three factors combined items indicating fair treatment, representation, and top management support for diversity and inclusion. Therefore, Model A separated the items into five factors indicating (a) employee involvement and learning and growth outcomes for diversity, (b) employee involvement and learning and growth outcomes for inclusion, (c) fair treatment (combined), (d) representation of diverse groups (combined), and (e) top management's support for diversity (combined). The other five-factor model (B) separated items indicating (a) employee involvement, (b) learning and growth outcomes, (c) fair treatment, (d) representation

of diverse groups, and (e) top management support for diversity. In Model B, all items for diversity and inclusion were combined. A sequential chi-square difference test ($\Delta\chi^2$), which is intended to assess changes in fit associated with models that have a nested or hierarchical relationship (Loehlin, 1992), was used to compare the three-factor model from Study 2 to the alternative models. A nested model is considered more suitable if its chi-square value is not statistically significantly worse compared with the less parsimonious model in which it is nested (Loehlin, 1992).

RESULTS

Fit indices for the proposed three-factor model as well as the alternative models are summarized in Table 4. As shown in the table, most of the models demonstrated only marginal levels of fit. However, one of the five-factor models (A) reached an acceptable level of fit to the data. This alternative model was made up of latent factors for fair treatment issues (Factor 1), the representation of diverse groups among stakeholders (Factor 2), top management's support for diversity (Factor 3), and employee participation and organizational outcomes (Factors 4 and 5). In the model, attributes for employee participation and organizational outcomes as indicators for diverse organizations (Factor 4) and for inclusive organizations (Factor 5) loaded on separate latent factors, thus resulting in a five-factor model. The paths from latent constructs to individual indicators were all significant ($p < .01$), with standardized loadings ranging from .35 to .87, as shown in Table 5.

Comparisons of this five-factor model (A) with the four-factor model showed a significant difference in chi-square ($\Delta\chi^2 = 1020.58$, 82 df), thus suggesting that this model could be differentiated from the less complex model. Because the less complex models are nested within the higher order alternative models, comparisons of model fit showed that one of the five-factor models (Model A) provided a more suitable explanation of the relationships among the data. Means, standard deviations, correlations, and reliabilities for the five latent factors are presented in Table 6.

DISCUSSION

The purpose of this article was to explore the meanings of diversity and inclusion or, more important, the attributes and practices to support each in organizations. The first study, the elicitation study, revealed conceptually distinct definitions of diversity and inclusion. Consistent with popular and scholarly diversity literature, definitions of diversity focused primarily on

TABLE 4
Structural Model Comparison Table

<i>Model</i>	χ^2	<i>CFI</i>	<i>IFI</i>	<i>RMSEA</i>	χ^2_{diff}
One-factor model	4445.26*	.65	.65	.13	
Two-factor model	3491.88*	.74	.74	.11	953.38**
Three-factor model (derived from Study 2)	2389.59*	.85	.85	.09	1102.29**
Four-factor model	2322.64*	.85	.85	.08	66.95**
Five-factor model (A)	1302.06*	.91	.91	.07	1020.58**
Five-factor model (B)	2197.05*	.86	.86	.08	(894.99)**

NOTE: Each model was compared with the preceding lower order model; both five-factor models were compared with the four-factor model. $N = 330$; CFI = comparative fit index; IFI = incremental fit index; RMSEA = root mean squared error of approximation.

heterogeneity and the demographic composition of groups or organizations, whereas definitions of inclusion focused on employee involvement and the integration of diversity into organizational systems and processes. In addition, the results highlighted a number of attributes for diversity and inclusion ranging from practices to increase the representation of different demographic groups to broader human resource initiatives intended to facilitate employee participation and engagement. Based on these results, I constructed an instrument to measure the degree to which each of these attributes supports diversity and inclusion in organizations.

In the second study, an empirical investigation of the reliability and factor structure of the new measure supported a three-factor model. One of the factors was represented by the attributes for inclusion. In other words, all of the attributes were described as characteristic of an inclusive organization. The other factors included the organizational attributes for diversity, although these factors differed in their foci. As shown by the results, one diversity factor included items relating to employee involvement, outcomes derived from diversity in organizations, and fair treatment. Accordingly, this factor seemed to encapsulate the discrimination-and-fairness and learning-and-effectiveness diversity paradigms articulated by Thomas and Ely (1996). It is interesting that the second diversity factor, which included items relating to the representation of demographic diversity at all levels and outside of an organization, seemed to incorporate Thomas and Ely's access-and-legitimacy paradigm. The second diversity factor was also represented by leader behaviors that exhibit a commitment to diversity. Thus, consistent with prior research that highlights the importance of top management attitudes and inter-

ventions in support of diversity to the effectiveness of diversity management programs (Konrad & Linnehan, 1995; Morrison, 1992), this factor highlights leadership's commitment to diversity as a key attribute of organizations that are supportive of diversity.

A third study was conducted to cross-validate the results for the measure of diversity and inclusion. Although the proposed three-factor model did not reach an acceptable level of fit, the results suggested that the data could be accounted for by an alternative five-factor model. Three of these factors (i.e., fairness, representation, leader commitment to diversity) were conceptually distinct and emerged from the factors revealed in Study 2. The remaining factors were identical in that they were represented by items relating to employee involvement and diversity-related outcomes such as learning, growth, and flexibility. As such, both factors incorporated indicators of inclusion similar to those described by Pelled et al. (1996) as well as Thomas and Ely's (1996) learning-and-effectiveness diversity paradigm. Although the factor-analytic separation of diversity and inclusion suggests that organizations following these two philosophies are distinct, the strong correlation between the factors indicates overlap between diversity and inclusion. Thus, the results of this study suggest that inclusive work practices and diversity-related outcomes may be characteristic of organizations that are diverse and/or inclusive. Further, given that diversity and inclusion items loaded similarly on the first three factors of the final factor structure, the findings may also suggest that the move from diversity to inclusion in organizations may primarily represent a change in language rather than a material change in diversity management practices.

In the creation of systems for equal employment opportunity and affirmative action, Konrad and Linnehan (1995) distinguish between identity-blind structures, or formalized human resource management practices designed

to ensure that decision-making processes are the same for each individual regardless of group identity, and identity-conscious structures, which are formalized human resource management practices that take both demographic group identity and individual merit into consideration. Although research shows that identity-conscious practices are positively related to the employment status of protected groups in organizations (Konrad & Linnehan, 1995), research has also highlighted backlash against such practices and diversity management programs in general (see Linnehan & Konrad, 1999). Given negative reactions to identity-conscious structures, organizations may be retreating from practices that focus on the specific and unique concerns of historically excluded groups in favor of more identity-blind structures that are responsive to the fears of exclusion and displacement among members of privileged groups (Konrad, 2003; Linnehan & Konrad, 1999).

As shown by the factors revealed in this study, the concepts of diversity and inclusion may potentially represent another iteration of the identity-blind versus identity-conscious debate. For example, the findings highlighted the importance of stakeholder diversity as well as fair treatment initiatives, which base decision making on group membership and, therefore, may be considered identity-conscious practices. In contrast, the inclusion factors highlighted broader human resource initiatives, such as collaborative work arrangements and conflict resolution processes, which are designed to involve all employees in organizational decision-making processes. As such, these organizational attributes may be considered identity-blind practices. Because a focus on inclusion in organizations may be similar to identity-blind structures by representing a more palatable approach to diversity management yet proving ineffective for promoting the interests of historically excluded groups, research is needed to understand the individual and organizational effects of managing diversity versus inclusion.

LIMITATIONS

One limitation of this research derives from the studies' samples. Although the results of Study 1 are consistent with related research, and both qualitative investigation and a review of the literature were used to derive lists of attributes for diversity and inclusion, the characteristics of the organizations that responded may limit the generalizability of the research findings. Specifically, because the diversity professionals in Study 1 were primarily from publicly traded organizations, the ability to say whether similar patterns of attributes would be highlighted in smaller and/or public organizations is limited. As these types of organizations may be constrained by resource

availability or budgetary issues, the comprehensiveness of their diversity management initiatives may be limited. Alternatively, the structure of such organizations—particularly, small organizations—may better facilitate inclusion and integration. Although people from a variety of organizations were surveyed and the sample sizes were sufficient to run exploratory and confirmatory factor analyses, some selection bias may also be inherent in the samples. Those responding to the survey may have had a direct interest in, or experience with, diversity issues or may represent organizations with formalized diversity initiatives. Similarly, each sample's familiarity with diversity management programs may have influenced the complexity of the factor structures. For example, OD professionals in Study 3 may have approached the survey from a systems perspective, thus resulting in a more nuanced or complex view of diversity and inclusion in organizations, whereas executives in Study 2 may have perceived a link between a broader array of organizational attributes and the management of diversity, thus resulting in a simpler factor structure. Because the results highlight the multifaceted nature of diversity and inclusion as well as variance in the interpretation of their meanings, further research is needed to examine attributes for each in different types of organizations and perceptions of each among different organizational groups.

The results of this study may also be limited by a potential biasing effect from providing definitions of diversity and inclusion to survey respondents in Studies 2 and 3. As discussed in the literature review as well as shown in the results of Study 1, there are many working definitions of diversity and inclusion. For example, Mor Barak et al. (1998) highlight practices for structurally including or excluding people from diverse backgrounds (e.g., employee network support groups and mentoring programs) as attributes for organizational inclusion, whereas Pelled et al. (1996) represent inclusion as employee involvement, access to information, and job security. Although providing definitions of the constructs of interest was beneficial in creating a consistent basis of interpretation among respondents, it also restricted the lens through which they interpreted the constructs of diversity and inclusion. Further, although the definitions used in the survey represented an amalgam of those included in prior diversity research as well as reported by respondents in Study 1, the design of the survey created an inherent distinction between the concepts of diversity and inclusion. Accordingly, such a distinction may have biased respondents' interpretation of the dimensions and, therefore, their ratings for each attribute—which may provide an alternative explanation for the existence of two identical factors (one for diversity and one for inclusion) in Study 2. Further research is needed to explore attributes for diversity and inclusion in organizations based on varying definitions of

these constructs. Given the lack of empirical research that demonstrates a relationship between diversity and organizational variables, it would also be useful to know if the dimensions revealed in this study are related to performance, agility, or other characteristics of organizations. Thus, the construct validity of the measure included here may also be strengthened by additional research to demonstrate its discriminant and convergent validity as well as the existence of a nomological network of relationships with other variables (Hinkin, 1995).

PRACTICAL IMPLICATIONS

Given the move from diversity to inclusion in the practitioner literature, the results of this study provide practitioners with an understanding of the concepts of diversity and inclusion and the attributes to support each in organizations. More specifically, the findings may help managers to characterize their approaches to diversity management based on implemented types of initiatives. For example, an organization may be typified as managing diversity with an emphasis on fairness issues and/or the representation of diverse groups at all internal levels and external to the organization. By understanding their current approach to diversity management, managers may be better able to identify strategies for creating more diverse and/or inclusive organizations, such as actions to demonstrate leadership's commitment to diversity or the institutionalization of participatory work systems. The measure included in this study may also serve as an assessment tool for understanding the degree to which employees perceive specific attributes to be representative of their business unit or organization. By linking such information to individual attitudes and behavior as well as various diversity metrics (e.g., job yields or attrition by demographic group, promotion rates, etc.), this tool may be useful for assessing and improving the effectiveness of diversity management initiatives. Further, by linking such information to unit-level outcomes (e.g., sales, customer satisfaction, etc.), this tool may be useful for conducting intraorganizational comparisons on the relationships between various approaches to diversity management and unit performance.

CONCLUSION

Given the emergence of a new rhetoric in the field of diversity, which replaces the term *diversity* with the term *inclusion*, this study comparatively investigates the meanings of diversity and inclusion in organizations. More important, this research links the scholarly and practitioner literature to empirically examine whether this move from diversity to inclusion represents a material change in diversity management practices or simply a change in lan-

guage. The results highlight a conceptual distinction between the concepts of diversity and inclusion as well as the attributes that support each in organizations. However, the results also suggest that the management of diversity is more complex than is currently articulated in both practitioner and scholarly research. Because there is a critical difference between merely having diversity in an organization's workforce and developing the organizational capacity to leverage diversity as a resource, this research provides some understanding of the different means through which diversity and inclusion may be facilitated or supported in organizations. From a theoretical perspective, this research underscores a need for further research to consider the concept as well as determinants and outcomes of inclusion as an approach to diversity management. Thus, by highlighting the similarities and differences between diversity and inclusion in organizations, both researchers and practitioners are better positioned to create, understand, and support changes needed to promote equality for historically disadvantaged groups as well as create organizations in which all employees can use their full portfolio of skills and talents.
